

Link_Budget_Modeling

February 23, 2025

1 An Earth-Venus-Earth Link Budget from Open Research Institute

This document contains a detailed link budget analysis for Earth-Venus-Earth (EVE) communications. It contains context, experimental worksheets for content that is planned to be moved into the EVELinkBudget class, and documentation.

The communications mode most similar to EVE is Earth-Moon-Earth (EME). EVE is more complex than EME communications due to several factors:

1. Much greater distances involved
2. Greater variability in the distances involved
3. Greater Doppler due to differences in how the orbital positions of Earth and Venus change with respect to each other when compared to the Earth and Moon
4. Different signal reflection characteristics from Venus compared to the Moon

Pointing and Tracking error, Doppler, and Mode Analysis need more attention and have their own cells below.

1.1 Imports and Dataclass Definition

We import the python modules that we need for the project.

We set up a dataclass called LinkParameters. We use numbers we have been given from Deep Space Exploration Society (DSES) who asked for assistance with this project. This first part of our analysis sets the values that are true for us regardless of the celestial target. For example, 1296 MHz (23cm band) is a common frequency for EME communications, and is the starting point for EVE. However, there's quite a bit of evidence showing that a frequency closer to 2450 MHz would be a better choice. The frequency can be changed in our LinkParameters data class.

```
[122]: # Cell 1: Imports and class definitions
import numpy as np
import matplotlib.pyplot as plt
from dataclasses import dataclass
from typing import Optional

@dataclass
class LinkParameters: #things that are true for us regardless of the target
    frequency_mhz: float = 1296.0 # Signal frequency
    tx_power_w: float = 1500.0 # Transmit power in watts
```

```

tx_antenna_diameter_m: float = 18.29 # Transmit antenna diameter
tx_antenna_efficiency: float = 0.69 # Transmit antenna efficiency
rx_antenna_diameter_m: float = 18.29 # Receive antenna diameter
rx_antenna_efficiency: float = 0.69 # Receive antenna efficiency
tx_line_loss_db: float = 0.5
rx_line_loss_db: float = 0.5
pointing_error_deg: float = 0.01 # Needs to be moved from worksheet to here
tracking_error_deg: float = 0.01 # Needs to be moved from worksheet to here
lna_noise_figure_db: float = 0.4
receiver_noise_bandwidth: float = 100e3 #
c: float = 299792458 # Speed of light in m/s
k: float = 1.380649e-23 # Boltzmann constant in J/K
t0: float = 290 # Reference temperature in K

```

1.2 EVELinkBudget Class

This link budget class is EVELinkBudget. It targets Venus as a reflective surface. We inherit all of our LinkParameters as params and can call upon them in this class. We then set up all our EVE/Venus specific values and define the functions that we need in order to calculate this specific link budget.

We add up all the gains and subtract the losses. This gives power at the receiver. We calculate the noise in our receive bandwidth, and subtract it from power at the receiver. This gives a carrier to noise ratio in dB. Our communications mode must be able to meet this CNR in order to close the link.

```
[123]: # Define the EVE link budget here - # Venus specific
class EVELinkBudget:
    def __init__(self, params: LinkParameters):
        self.params = params

        # Venus characteristics
        self.venus_radius_km = 6051.8 # Venus radius in km
        self.venus_radar_albedo = 0.152 # Venus radar albedo (Radio Echo)
        ↪Observations of Venus and Mercury at 23 cm Wavelength, 1965)
        self.venus_atm_loss_db = -0.5 # Additional loss for Venus atmosphere
        ↪(why same as Earth? Is this not already in radar albedo?)

    def wavelength(self) -> float:

    'rx_power_dbw': rx_power,
    'noise_dbw': noise_dbw,
    'cnr_db': cnr
}

```

1.3 Link Budget Calculator Setup

We fetch all the LinkParameters and then create a calculator instance by saying EVELinkBudget(params). We've specified the class of EVELinkBudget. We're now creating an object where we can call the various methods inside of that class, which includes our calculate_link_budget(). Since the distance to Venus varies quite a bit, this is a parameter we need to provide.

```
[124]: # Cell 2: Create calculator instance
params = LinkParameters()
calculator = EVELinkBudget(params)
```

1.4 Effect of Distance on Received Power and Carrier-to-Noise Ratio

This part of the sheet shows the variation in received power and in CNR due to the variation in distance from Earth to Venus.

```
[125]: # Cell 3: Calculate for Earth-Venus distances
min_distance_km = 38_000_000 # Minimum Earth-Venus distance
max_distance_km = 261_000_000 # Maximum Earth-Venus distance

# Create distance array for plotting
distances = np.linspace(min_distance_km, max_distance_km, 1000)
cnrs = []
rx_powers = []

for dist in distances:
    results = calculator.calculate_link_budget(dist)
    cnrs.append(results['cnr_db'])
    rx_powers.append(results['rx_power_dbw'])
```

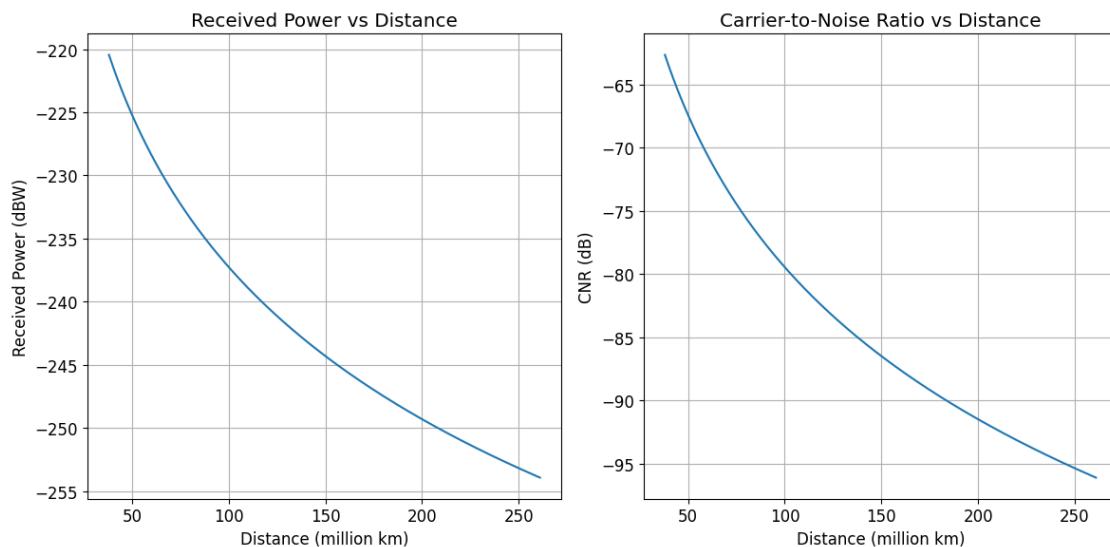

```
[126]: # Cell 4: Create plots
plt.figure(figsize=(12, 6))
plt.subplot(1, 2, 1)
plt.plot(distances/1e6, rx_powers)
plt.grid(True)
```

```

plt.xlabel('Distance (million km)')
plt.ylabel('Received Power (dBW)')
plt.title('Received Power vs Distance')

plt.subplot(1, 2, 2)
plt.plot(distances/1e6, cnrs)
plt.grid(True)
plt.xlabel('Distance (million km)')
plt.ylabel('CNR (dB)')
plt.title('Carrier-to-Noise Ratio vs Distance')
plt.tight_layout()
plt.show()

```

1.5 Pointing and Tracking Error Worksheets

Dish antennas have a narrow beamwidth. Pointing and tracking errors cost us in our link budget. This section models the pointing and tracking errors so that those amounts can be included in the link budget calculations. We return the pointing loss that corresponds to 1dB and 3dB signal loss. We plot pointing error vs. loss in a chart.

```

[127]: # Cell 5: Parameters for dish analysis of pointing error
class AntennaAnalysis:
    def __init__(self, params: LinkParameters):
        self.params = params

    def wavelength(self) -> float:
        """Calculate wavelength in meters from frequency in MHz"""
        frequency_hz = self.params.frequency_mhz * 1e6 # Convert MHz to Hz
        return self.params.c / frequency_hz

```

```

def beamwidth_deg(self) -> float:
    """Calculate 3dB beamwidth in degrees"""
    # Using 1.22 /D formula for circular aperture
    return np.degrees(1.22 * self.wavelength() / self.params.
        tx_antenna_diameter_m)

def pointing_loss_vs_error(self, max_error_deg: float = 0.5):
    """Calculate pointing loss for range of pointing errors"""
    errors = np.linspace(0, max_error_deg, 100)
    losses = -12 * (np.radians(errors) / np.radians(self.
        beamwidth_deg()))**2
    return errors, losses

# Create analyzer using params from link budget
analyzer = AntennaAnalysis(params)

# Calculate key parameters
beamwidth = analyzer.beamwidth_deg()
print(f"For a {analyzer.params.tx_antenna_diameter_m:.2f}m dish at {analyzer.
    params.frequency_mhz:.1f} MHz:")
print(f"3dB Beamwidth: {beamwidth:.3f} degrees")
print(f"Recommended max tracking error (1dB loss): {beamwidth/5.66:.3f}_
    degrees")
print(f"Recommended max tracking error (3dB loss): {beamwidth/2:.3f} degrees")

```

For a 18.29m dish at 1296.0 MHz:

3dB Beamwidth: 0.884 degrees
 Recommended max tracking error (1dB loss): 0.156 degrees
 Recommended max tracking error (3dB loss): 0.442 degrees

Let's explain these calculations because I didn't find it intuitive at first.

1. `beamwidth = analyzer.beamwidth_deg()`
 - This calculates the 3dB beamwidth (where power drops to half)
 - Uses the formula $1.22 * \pi / D$ for a circular aperture
 - This is the “width” of your main beam
2. The tracking error recommendations come from the pointing loss formula we used earlier:

```
pointing_loss = -12 * (error_angle / beamwidth)**2
```

This wasn't intuitive but it's in a lot of papers and seems legit.

3. Working backwards from this formula:

- For 1dB loss: $-1 = -12 * (\text{error}/\text{beamwidth})^{**2}$
- Solving for error: $\text{error} = \text{beamwidth}/\sqrt{12} \cdot \text{beamwidth}/5.66$
- For 3dB loss: $-3 = -12 * (\text{error}/\text{beamwidth})^{**2}$

- Solving for error: $\text{error} = \text{beamwidth}/2$

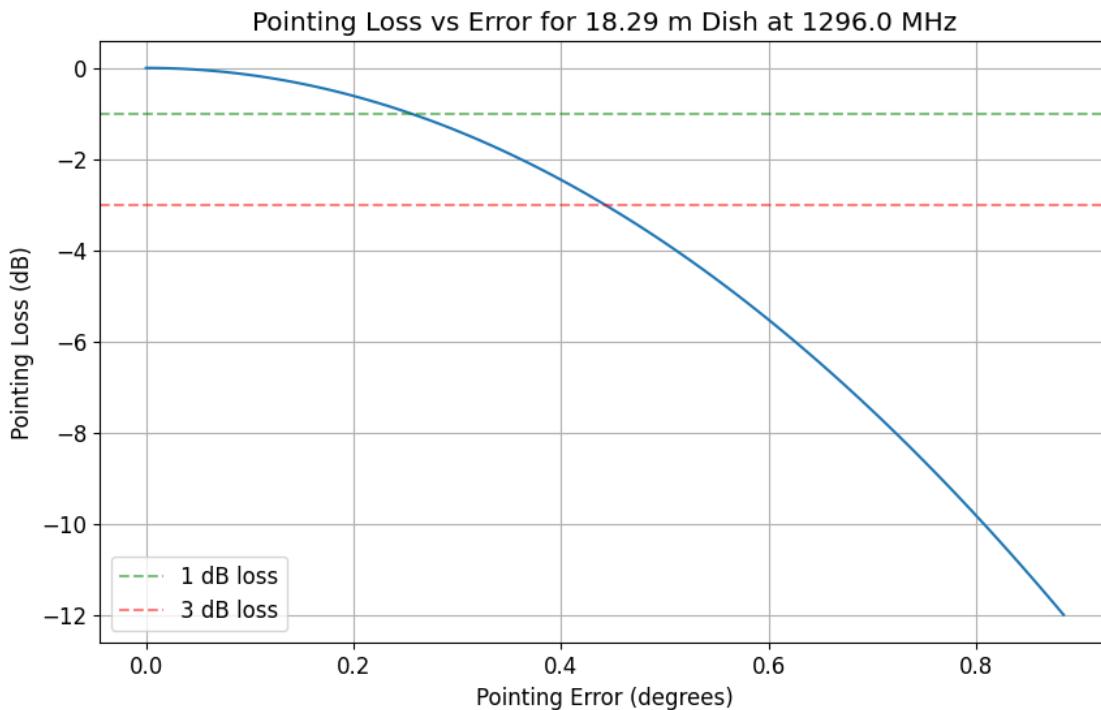

So if your beamwidth is (for example) 0.6 degrees:

- For 1dB loss: max error should be $0.6^\circ/5.66 = 0.106^\circ$
- For 3dB loss: max error should be $0.6^\circ/2 = 0.3^\circ$

```
[128]: # Plot pointing loss vs error
errors, losses = analyzer.pointing_loss_vs_error(max_error_deg=beamwidth)

plt.figure(figsize=(10, 6))
plt.plot(errors, losses)
plt.grid(True)
plt.xlabel('Pointing Error (degrees)')
plt.ylabel('Pointing Loss (dB)')
plt.title(f'Pointing Loss vs Error for {params.tx_antenna_diameter_m:.2f} m Dish at {analyzer.params.frequency_mhz:.1f} MHz')

# Add horizontal lines for common loss thresholds
plt.axhline(y=-1, color='g', linestyle='--', alpha=0.5, label='1 dB loss')
plt.axhline(y=-3, color='r', linestyle='--', alpha=0.5, label='3 dB loss')
plt.legend()
plt.show()
```

1.6 Pointing Error as a function of Tracking Error Normalized by Beamwidth

This is an experimental section to try and quantify the tracking error. Pointing error and tracking error are two different things, but notice that we get the same numerical results. Feedback here welcome and encouraged.

```
[129]: # Cell 5: dish analysis of tracking error
#The visualization shows:
#The blue curve is the pointing loss vs tracking error (normalized to beamwidth)
#The green point shows where tracking error = beamwidth/5.66, giving 1 dB loss
#The red point shows where tracking error = beamwidth/2, giving 3 dB loss

#If your tracking error is less than beamwidth/5.66, your pointing loss is less
#than 1 dB
#At beamwidth/2, you've lost half your power (3 dB)
#The loss increases with the square of the error

def calculate_pointing_loss(error_angle, beamwidth):
    """Calculate pointing loss in dB given error angle and beamwidth"""
    return -12 * (error_angle / beamwidth)**2

# Create a range of error angles as fraction of beamwidth
error_fractions = np.linspace(0, 1, 100)

# Calculate losses
losses = calculate_pointing_loss(error_fractions, 1)

# Create the plot
plt.figure(figsize=(12, 8))

# Main loss curve
plt.plot(error_fractions, losses, 'b-', linewidth=2, label='Pointing Loss')

#Calculate losses at our specific points
loss_at_166 = calculate_pointing_loss(1/5.66, 1)
loss_at_half = calculate_pointing_loss(1/2, 1)

print(f"Loss at error/beamwidth = 1/5.66: {loss_at_166:.2f} dB")
print(f"Loss at error/beamwidth = 1/2: {loss_at_half:.2f} dB")

# Add markers for specific loss points
plt.plot(1/5.66, loss_at_166, 'go', markersize=10, label='1 dB Loss Point')
plt.plot(1/2, loss_at_half, 'ro', markersize=10, label='3 dB Loss Point')

# Add horizontal lines for loss levels
plt.axhline(y=loss_at_166, color='g', linestyle='--', alpha=0.5)
plt.axhline(y=loss_at_half, color='r', linestyle='--', alpha=0.5)
```

```

# Add vertical lines for error ratios
plt.axvline(x=1/5.66, color='g', linestyle='--', alpha=0.5)
plt.axvline(x=1/2, color='r', linestyle='--', alpha=0.5)

# Customize the plot
plt.grid(True, alpha=0.3)
plt.xlabel('Tracking Error / Beamwidth Ratio')
plt.ylabel('Pointing Loss (dB)')
plt.title('Pointing Loss vs Tracking Error\n(as fraction of beamwidth)')

#Calculate losses at our specific points
loss_at_166 = calculate_pointing_loss(1/5.66, 1)
loss_at_half = calculate_pointing_loss(1/2, 1)

print(f"Loss at error/beamwidth = 1/5.66: {loss_at_166:.2f} dB")
print(f"Loss at error/beamwidth = 1/2: {loss_at_half:.2f} dB")

# Add text annotations
plt.annotate('1 dB loss at\nerror = beamwidth/5.66',
            xy=(1/5.66, loss_at_166), xytext=(0.1, -2),
            arrowprops=dict(facecolor='black', shrink=0.05))

plt.annotate('3 dB loss at\nerror = beamwidth/2',
            xy=(1/2, loss_at_half), xytext=(0.3, -5),
            arrowprops=dict(facecolor='black', shrink=0.05))

plt.legend()

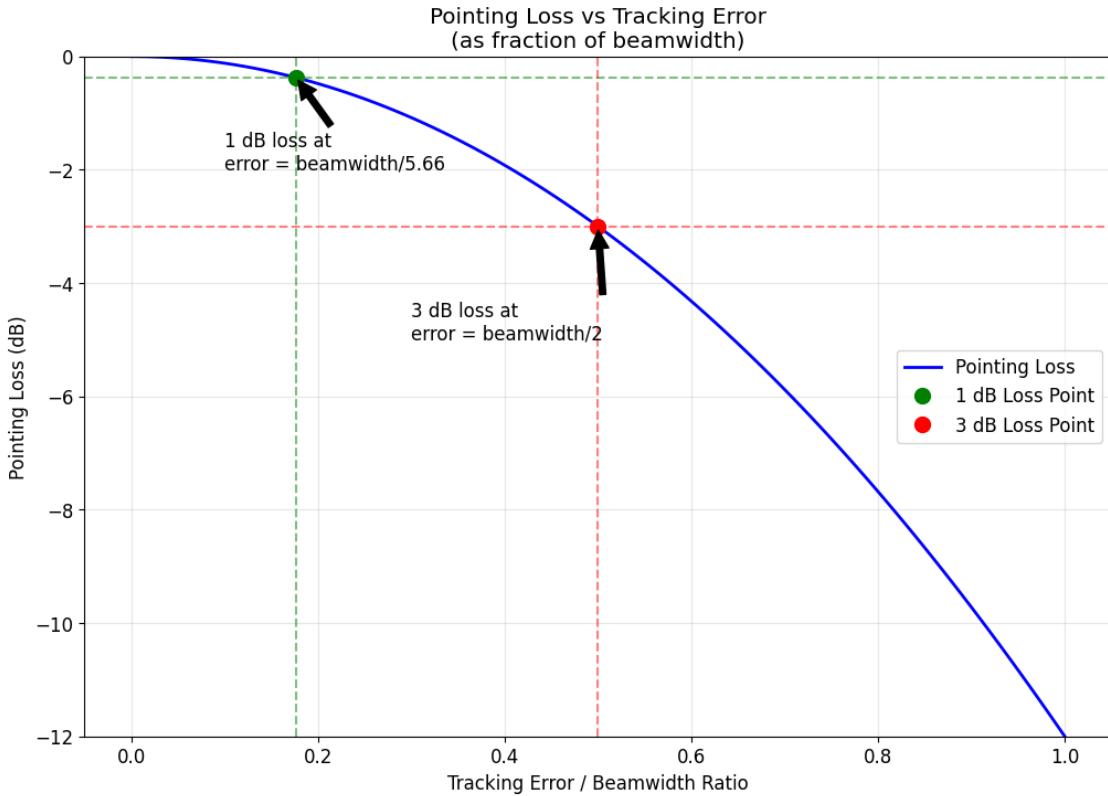

# Set y-axis limits to focus on relevant range
plt.ylim(-12, 0)

plt.show()

# Print example calculations for your specific dish
beamwidth = analyzer.beamwidth_deg()
print(f"\nFor your {params.tx_antenna_diameter_m:.2f}m dish at {params.
    ↪frequency_mhz/1e6:.1f} MHz:")
print(f"Beamwidth: {beamwidth:.3f}°")
print(f"Max tracking error for 1 dB loss: {beamwidth/5.66:.3f}°")
print(f"Max tracking error for 3 dB loss: {beamwidth/2:.3f}°")

```

Loss at error/beamwidth = 1/5.66: -0.37 dB
 Loss at error/beamwidth = 1/2: -3.00 dB
 Loss at error/beamwidth = 1/5.66: -0.37 dB
 Loss at error/beamwidth = 1/2: -3.00 dB

For your 18.29m dish at 0.0 MHz:

Beamwidth: 0.884°

Max tracking error for 1 dB loss: 0.156°

Max tracking error for 3 dB loss: 0.442°

1.7 Link Budget at Minimum and Maximum Distance

Here is the CNR at a particular receiver bandwidth for minimum and maximum distance from Earth to Venus.

```
[131]: # Cell 6: Print detailed results for minimum and maximum distances
min_results = calculator.calculate_link_budget(min_distance_km)
max_results = calculator.calculate_link_budget(max_distance_km)

print(f"Link Budget at Minimum Distance (38 million km) at {params.
    ↪receiver_noise_bandwidth/1e6} MHz receiver bandwidth")
for key, value in min_results.items():
    print(f"{key}: {value:.2f}")

print(f"\nLink Budget at Maximum Distance (261 million km) at {params.
    ↪receiver_noise_bandwidth/1e6} MHz receiver bandwidth")
```

```

for key, value in max_results.items():
    print(f"{key}: {value:.2f}")

```

Link Budget at Minimum Distance (38 million km) at 0.1 MHz receiver bandwidth

```

cnr_db: -96.12

```

1.8 What Communication Modes Will Work?

This section is an attempt to show which communications modes close the link. We have CNR and a receive bandwidth. We want to create a visualization of the modes that will close the link.

```
[132]: # Dictionary of common communication modes and their minimum required CNR
comm_modes = {
    'Q65-60A': -26,  # Best for minimal spread
    'Q65-60B': -25,  # For moderate spread
    'Q65-60C': -24,  # For higher spread
    'Q65-60D': -23,  # For very high spread
    'Q65-60E': -22,  # For extreme spread
    'JT65': -10,
    'WSPR': -8,
    'CW (Morse)': 0,
    'PSK31': 3,
    'RTTY': 8,
    'SSB Voice': 10,
    'FM Voice': 15,
}
```

```

'SSTV': 16,
'High Speed Digital': 20,
'HD Video': 25
}

# Get your link budget CNR values from earlier calculations
min_results = calculator.calculate_link_budget(min_distance_km)
max_results = calculator.calculate_link_budget(max_distance_km)

min_cnr = min_results['cnr_db']
max_cnr = max_results['cnr_db']

# Create visualization
plt.figure(figsize=(12, 8))

# Plot CNR requirements as horizontal lines
modes = list(comm_modes.keys())
cnrs = list(comm_modes.values())

# Create range for your link's CNR
cnr_range = np.linspace(min_cnr, max_cnr, 100)
plt.fill_between([0, len(modes)-1], min_cnr, max_cnr, alpha=0.2, color='blue',
                 label=f'Your Link CNR Range: {min_cnr:.1f} to {max_cnr:.1f} dB')

# Plot mode requirements
plt.plot(range(len(modes)), cnrs, 'ro-', label='Required CNR')

# Customize plot
plt.grid(True, alpha=0.3)
plt.xlabel('Communication Mode')
plt.ylabel('Required CNR (dB)')
plt.title(f'Communication Modes vs Required CNR\nCompared to Your Link\u2022 Budget\nAt {params.receiver_noise_bandwidth} Hz Receiver Noise Bandwidth')

# Rotate x-axis labels for better readability
plt.xticks(range(len(modes)), modes, rotation=45, ha='right')

plt.legend()
plt.tight_layout()
plt.show()

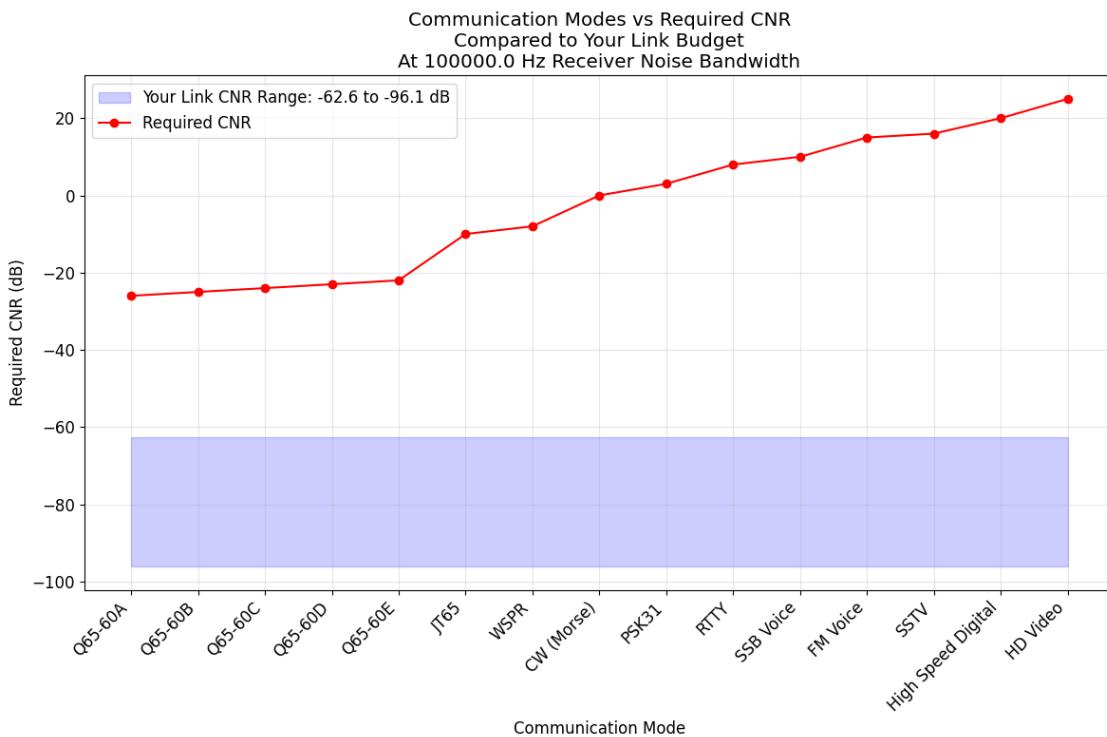

# Print analysis
print("\nCommunication Mode Analysis:")
print(f"Your link CNR range: {min_cnr:.1f} dB to {max_cnr:.1f} dB")
print("\nPossible communication modes:")
for mode, required_cnr in comm_modes.items():

```

```

if max_cnr >= required_cnr:
    margin_best = max_cnr - required_cnr
    margin_worst = min_cnr - required_cnr
    status = " Always possible" if min_cnr >= required_cnr else "~"
    ↵Sometimes possible"
    print(f"{{mode:15} {{status:20}} (Margin: {margin_worst:.1f} to"
    ↵{margin_best:.1f} dB)")
else:
    print(f"{{mode:15} Not possible")

```

Communication Mode Analysis:

Your link CNR range: -62.6 dB to -96.1 dB

Possible communication modes:

Q65-60A	Not possible
Q65-60B	Not possible
Q65-60C	Not possible
Q65-60D	Not possible
Q65-60E	Not possible
JT65	Not possible
WSPR	Not possible
CW (Morse)	Not possible
PSK31	Not possible

RTTY	Not possible
SSB Voice	Not possible
FM Voice	Not possible
SSTV	Not possible
High Speed Digital	Not possible
HD Video	Not possible

1.9 How much Doppler do we Have?

We will have to anticipate and “track out” Doppler. How much Doppler do we have to deal with? This section quantifies how much we have, and also shows how much Doppler spread our potential communications modes can tolerate “on their own”. We want to compare this to the “expected” Doppler of the link. Right now, it is set to 10% of maximum Doppler. We read that several hundred kHz of Doppler between Earth and Venus can occur.

To get our maximum result, we calculated a maximum relative velocity. This calculation needs review.

The “expected” Doppler is simply 10% of the maximum, which also needs review.

This section needs some attention from someone that knows how to show Earth-Venus Doppler so we can gain better expectations of the requirements of the link.

```
[133]: class AntennaAnalysis:
    def __init__(self, params: LinkParameters):
        self.params = params

    class DopplerAnalysis:
        def __init__(self, params: LinkParameters):
            self.params = params

        def calculate_doppler_shift(self, velocity_ms: float) -> float:

1.12 System Noise Temperature Worksheet (Draft)

Trying to recreate the 70 k Tsys from the DSES worksheet. Numbers don't match so we should figure out why.

Some notes on trying to move to a higher frequency, and whether the surface RMS estimation of 0.3mm could "hold":

At 1296 MHz:

Surface efficiency 98%

Very good performance, minimal scatter loss.

At 2450 MHz:

Surface efficiency 98%

Does not seem to present a problem.

Also, $f_{max} = c / (16 \times RMS)$ as a guideline, which gives a really large number.

```
